# CS 61A Discussion 2

**Environment Diagrams and Recursion** 

Raymond Chan Discussion 121 UC Berkeley

#### Announcements

- Project 1 Hog due tonight
  - tinyurl.com/61a-unstuck
- Guerrilla Section on Recursion 2/7 10am-noon
- CSM small group tutoring sections sign ups
  - csmscheduler.herokuapp.com

# Environment Diagrams

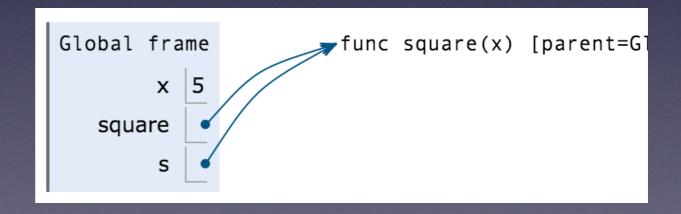

- Environment diagrams allow us to keep track of variables that have been defined and the values they are bound to.
- Assignment Statements
- Def Statements
- Function Calls
- Lambda Expressions

# Assignment Statements

- Evaluate the expression on the right hand side of the = sign.
  - Look up variable names in the current frame. If it does not exist, look up in the parent frame.
  - Evaluate primitive expressions and operations
  - Evaluate call expressions

# Assignment Statements

- Write the variable name and the expression value in the current frame.
- If the expression is a function, use an arrow.

#### Def Statements

- Write the function name in the frame and point it to the function object.
- Function object contains the function signature and the parent frame.
- The parent frame is the frame in which the frame is defined.
- Do not evaluate the body of the function at this time.

#### Def Statements

 Function signature contains the function's intrinsic name and the formal parameters.

```
1 x = 5

→ 2 def square(x):
3 return x**2
4
```

```
Global frame

x 5

square
```

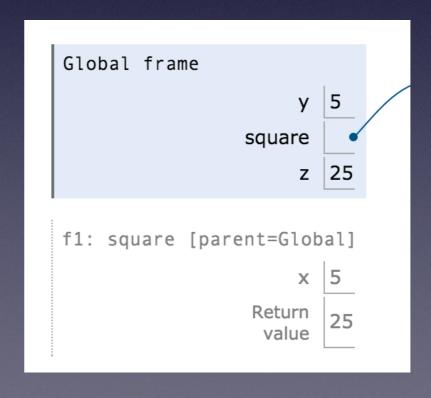

# Call Expressions

- After evaluating operator and all the operands, we apply the arguments to the function to make a function call.
- Draw a new frame with a unique frame index, the function's intrinsic name, and the parent frame.
- Bind the formal parameters to the argument(s) passed in.
- Evaluate the body of the function

# Call Expressions

- Remember to denote the return value. If a function does not return anything, the return value is by default **None**.
- If we are assigning a variable to a call expression, assign the return value to the variable in the frame of the call expression.

```
1  y = 5
2  def square(x):
3    return x**2
4
→ 5  z = square(y)
```

#### Lambda Functions

- lambda <parameters>: <body>
- There can be multiple parameters delimited by commas.
  - lambda x, y, z: <body>
- Lambda functions create function objects with the function name as λ.
- Create the function object in the environment diagram even if it is not assigned to a variable.

#### Lambda Functions

- Lambda functions cannot be accessed if it is not assigned to variables either by
  - using an explicit assignment statement or
  - passing the lambda function into another function's argument.

```
1 square = lambda x: x * x
2 def f(x):
3     def g(y, z):
4         return x(y, z)
5         return g
6

→ 7 f(lambda a, b: a + b)
```

```
Global frame \rightarrow func \lambda(x) <line 1> [parent=Global] square \rightarrow func f(x) [parent=Global] func \lambda(a, b) <line 7> [parent=Global] func g(y, z) [parent=f1] g Return value
```

#### Function Call vs. Function

- Variables can be assigned to the return value of a function call or the function object itself.
- Remember that variables are assigned to whatever the result of evaluating the right hand side is pointing at.

```
1 square = lambda x: x * x
2 four = square(2)
3 f = square

→ 4 nine = f(3)
```

```
Global frame
                                         ⇒func λ(x)
                      square
                         four
                        nine
f1: λ <line 1> [parent=Global]
f2: λ <line 1> [parent=Global]
                        value
```

- A recursive function is a function that calls itself.
- Three common steps
  - Figure our your base case(s)
  - Make the problem smaller and make a recursive call with that simpler argument
  - Use your recursive call to solve the full problem

- Base cases are there to stop the recursion.
- No base case —> continue making recursive calls forever

```
def factorial(n):
    if n == 0 or n == 1:
        return 1
    else:
        return n * factorial(n-1)
```

- Find a smaller problem for the recursive call.
- Make sure the problem is getting smaller toward the base case.
- Call the recursive function with this smaller argument.

```
def factorial(n):
    if n == 0 or n == 1:
        return 1
    else:
        return n * factorial(n-1)
```

- Take the *leap of faith* and trust that your recursive function is correct on the smaller argument.
- Knowing that the recursive call returns what you want, how can you solve the bigger problem?

```
def factorial(n):
    if n == 0 or n == 1:
        return 1
    else:
        return n * factorial(n-1)
```

factorial(5)

```
factorial(5)

$\int \text{5 * factorial(4)}$
```

```
factorial(5)

5 * factorial(4)

4 * factorial(3)
```

```
factorial(5)

5 * factorial(4)

4 * factorial(3)

3 * factorial(2)
```

```
factorial(5)

5 * factorial(4)

4 * factorial(3)

3 * factorial(2)

2 * factorial(1)
```

```
factorial(5)

5 * factorial(4)

4 * factorial(3)

3 * factorial(2)

2 * factorial(1)
```

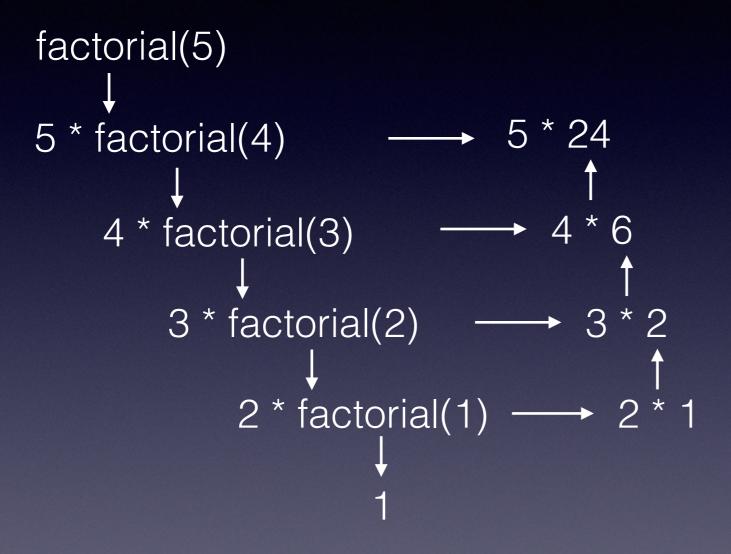

```
factorial(5)

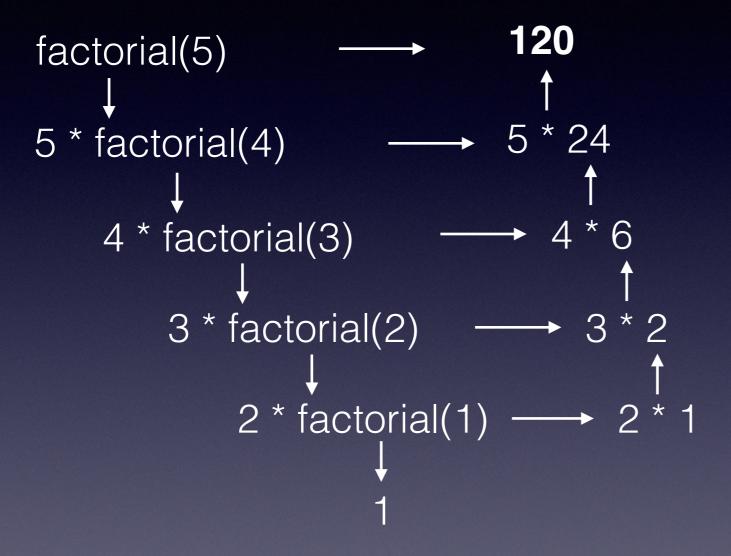

5 * factorial(4)

4 * factorial(3)

3 * factorial(2)

2 * factorial(1) \leftarrow 2 * 1
```

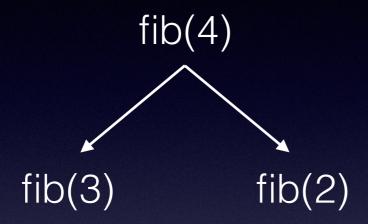

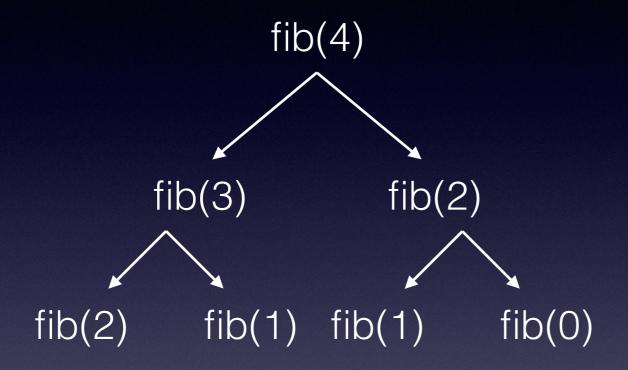

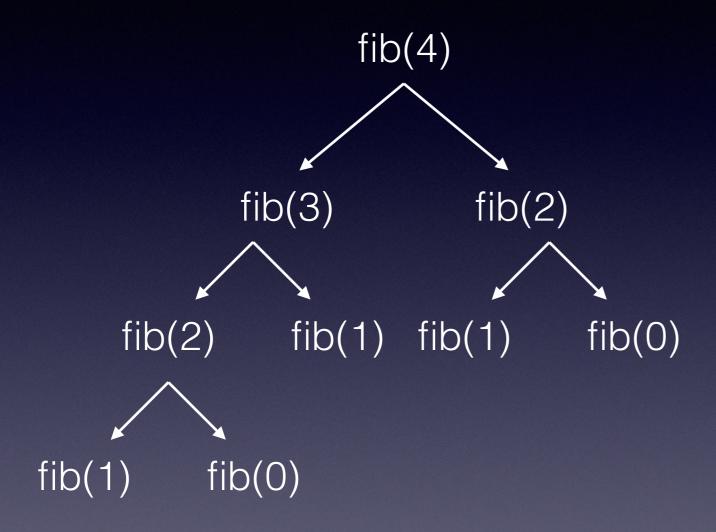

- Recursive functions that make more than one recursive call in its recursive case.
- Example: fibonacci sequence

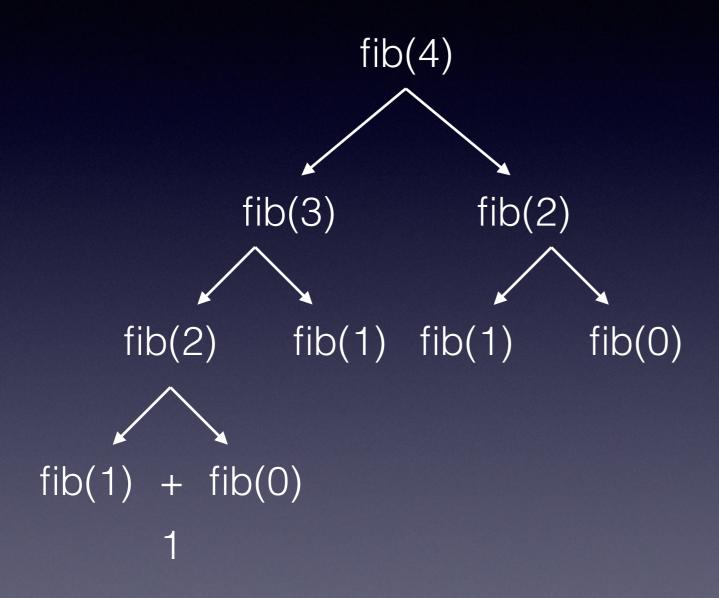

```
def fib(n):
    if n == 0:
        return 0
    elif n == 1:
        return 1
    else:
        return fib(n - 1) + fib(n - 2)
```

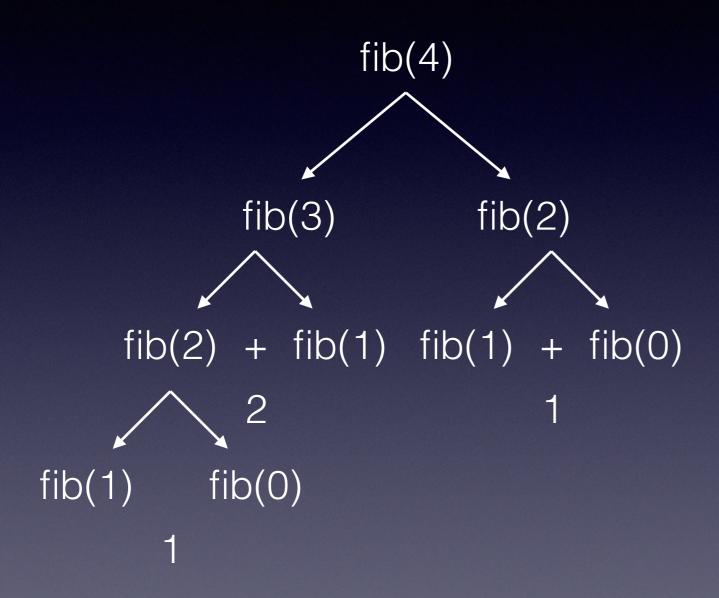

fib(4)

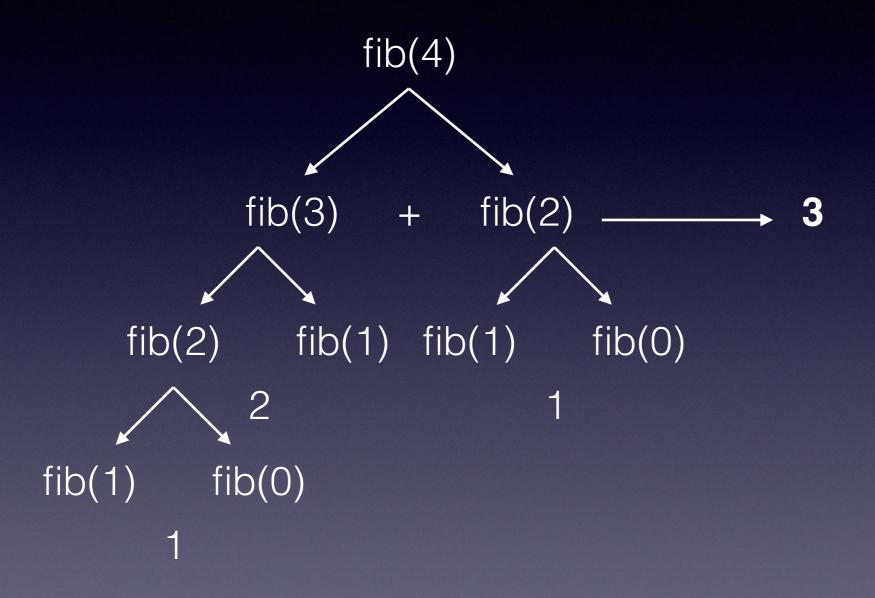

## Worksheet

- 2.1 Cool recursion questions!
  - q1 q2
- Tree recursion
  - q1

# Recap

- Environment diagrams allow us to keep track of a variables and their values.
- Recursion functions call themselves.
- Tree recursive functions call themselves multiple times from one frame.
